Experiment Motivation

Testing the viability of an adjustable magnetic mangle Halbach array as a proof of concept for electromagnet alternatives in accelerators

Goals:

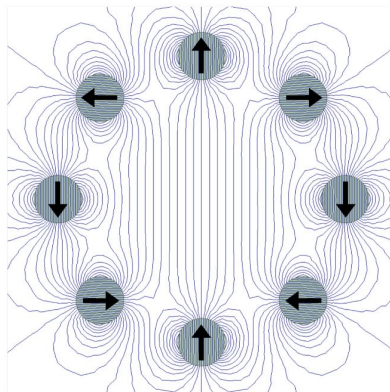

- Replace electromagnets, whose **energy usage is a contributor to climate change**
- **Safer** to use near other electronics, like pacemakers, due to small external field
- Modular design: **cost effective** (compared to electromagnets), reduces waste, convenient

Magnet design: introduction

A mangle of 8 permanently diametrically-magnetized cylinders arranged in a circle to produce either a dipole or quadrupole field

Modularity:

- By rotating the magnets, the mangle can be switched: dipole \leftrightarrow quadrupole configurations
- By moving the magnets radially inward or outward, the field strength can be adjusted

(a) Dipole arrangement

(b) Quadrupole arrangement

Magnet design: determining optimal cylinder number

- As N , the number of magnets, increases, deviation from ideal magnetic field decreases, but for very large N rotating each magnet becomes impractical
- Performed simulations in ANSYS Maxwell and quantified the deviation of the mangle's field from the corresponding ideal field using RAE

$$\text{RAE} = \frac{\sqrt{\sum_{i=1}^n |\vec{B}_{mangle_i} - \vec{B}_{ideal_i}|^2}}{\sqrt{\sum_{i=1}^n |\vec{B}_{ideal_i}|^2}}$$

\vec{B}_{mangle_i} and \vec{B}_{ideal_i} are the mangle field and corresponding ideal field vectors at a given sample point i out of n total sample points.

Magnet design: determining optimal cylinder number

- Performed simulations in ANSYS Maxwell and quantified the deviation of the mangle's field from the corresponding ideal field using Relative Absolute Error (RAE)

Final Stationary Array

- **Goal:** test the **utility of Halbach** arrays as alternatives to electromagnets, and study the effect of a **changing radius**
- Two Halbach **dipole arrangements**, stronger magnets → larger magnetic field

Successfully Used in Beam Area

Original Mangle Design

- **Goal:** create on-the-fly radial and rotational adjustment of our magnet
- **Updates:** experiment handling safety, structural safety

Final Experiments at CERN:

- Explore stationary Halbach arrays
- Update mangle with improved lock mechanism

Final Adjustable Array (Design)

- **Goal:** provide a **proof of concept** of a fully adjustable magnetic mangle
- **Magnets within casings**, prevent involuntary translational/rotational movement
- Rotation → **casings slide radially**, octagonal pins

Key can be inserted and rotated to lock in place

Magnet Inside

Small Radius

Large Radius

Final Adjustable Array (Fabricated)

Successfully Used in Beam Area

Setup 2: Characterise Halbach Magnet

Experiment design: Detector Setup

Type	Distance From Target [m]		Device Name	Signal
QPole (Focusing)	34.501		QF [T10.QFN035]	
Scintillator	35.921		S0 [ZT10.BXSCI036]	S0
QPole (De-Focusing)	37.520		QD [T10.QDN038]	
Cherenkov Thresh (Hi)	39.454		XCET0 [ZT10.XCET040]	C0
Dipole	40.217		DH T10.DHZ040]	
Door	42.000		Door / Begin of Zone	
Cherenkov Thresh (Lo)	43.640		XCET1 [ZT10.XCET043]	C1
Scintillator	44.090		S1 [ZT10.BXSCI044]	S1
Halo Counter (as veto) or very small scintillator as Coincidence to only trigger on particles that go through the magnet's aperture			DWC0 DWC1	L0, R0, U0, D0, AV0, AH0 L1, R1, U1, D1, AV1, AH1
			S2 (HALO/SMALL)	S1
			DUT / Halbach Magnet	
			in this setup, we can continue to take data with the cherenkov detectors for the beam composition experiment while fully characterising the magnet in all its modes (Dipole, Quadrupole, Mixed?)	
			DWC2 DWC3	L2, R2, U2, D2, AV2, AH2 L3, R3, U3, D3, AV3, AH3
S0 <-> S3: ToF measurement for all particles			S3	S3
			Calorimeter	CA0, ... CA8
S4 should only detect muons			S4	S4

Stationary Mangle Longitudinal Flux Density Profile

- Plateau in middle of mangle cavity
- Flux density drops off rapidly outside of mangle
- Linear interpolation

Flux Density (T) vs. x position (m)

Predicted Magnet Deflection

$$r(x) = \frac{p}{qB(x)}$$

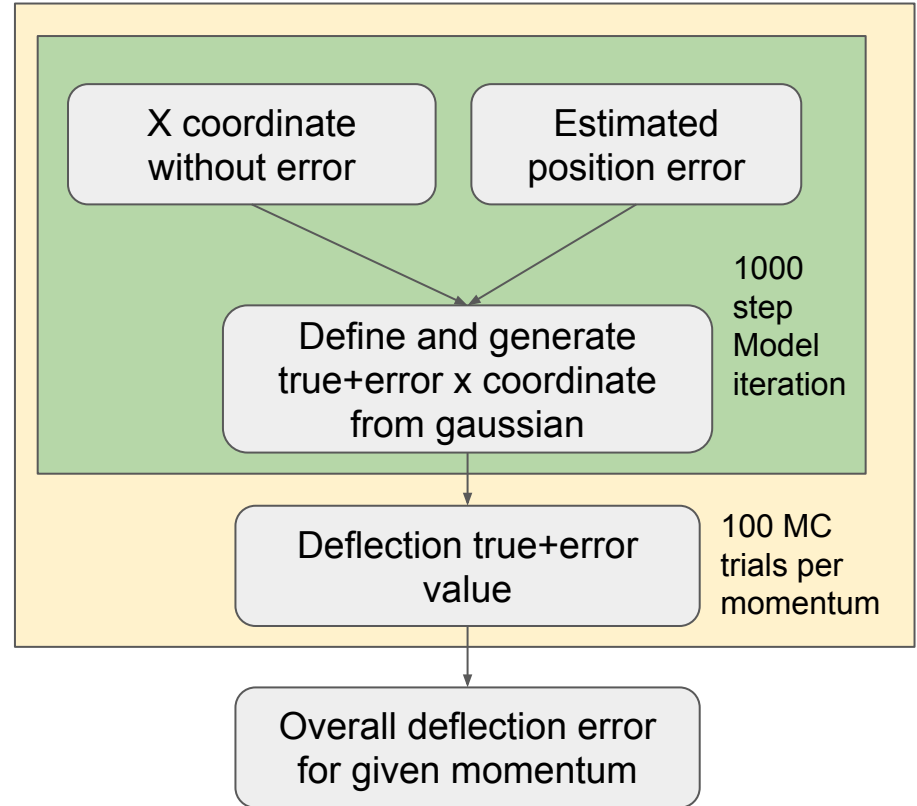

$$\theta_n = \arcsin \left(\frac{x_{n+1} - x_n + r_n \cos \left(\frac{\pi}{2} - (\theta_{n-1} + \theta_{n-2} + \theta_{n-3} + \dots + \theta_1) \right)}{r_n} \right) - (\theta_{n-1} + \theta_{n-2} + \theta_{n-3} + \dots + \theta_1)$$

$$y_{n+1} - y_n = r_n \left(\cos (\theta_{n-1} + \theta_{n-2} + \theta_{n-3} + \dots + \theta_1) - \cos (\theta_n + \theta_{n-1} + \theta_{n-2} + \theta_{n-3} + \dots + \theta_1) \right)$$

- Given flux density $B(x)$, radius of curvature $r(x)$ is obtained
- Iterate over circular arcs (1000 steps)
- Propagate to DWC2 position after exiting magnet field

Predicted Magnet Deflection - MC Error Propagation

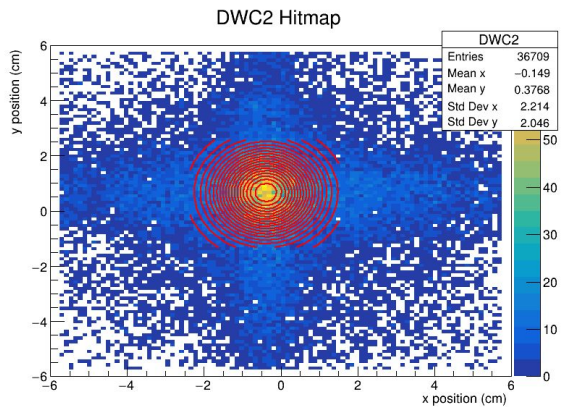

- Gaussian distributions were generated for each source of error (e.g. x-coordinate measurement, teslameter flux density measurement, linear interpolation error).
- Truth+errors were generated according to the gaussian distribution for each line of iteration.
- 100 trials for each momentum value, true+error values were inputted to the model, and stdevs were calculated for the output deflection distributions.

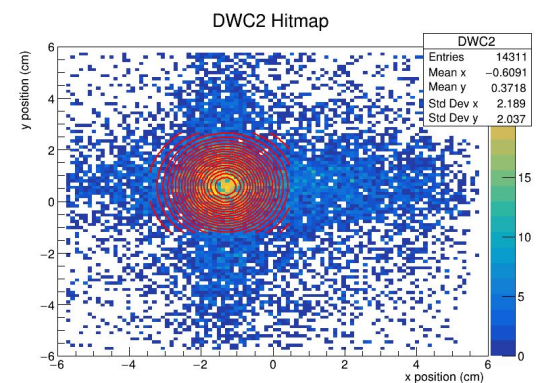

Results

± 8 GeV DWC Magnet Effects ($r_{\text{mag}} = 2.5$ cm)

No magnet

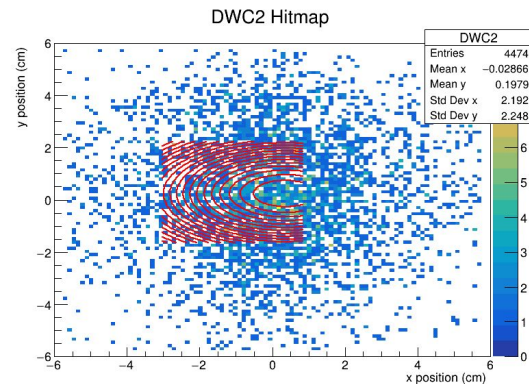

Magnet

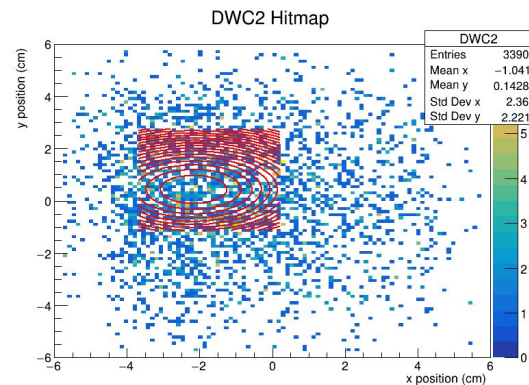

± 2 GeV DWC Magnet Effects ($r_{\text{mag}} = 3.5$ cm)

No magnet

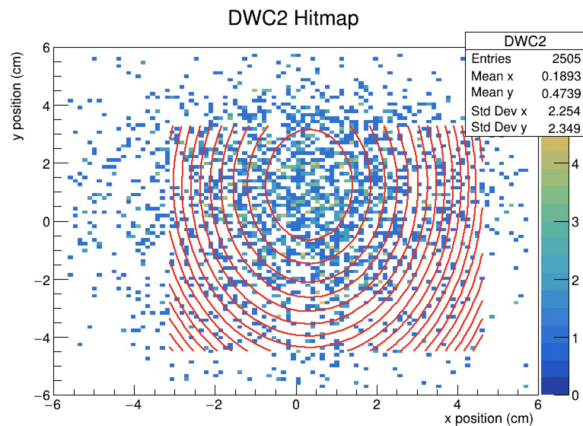

Magnet

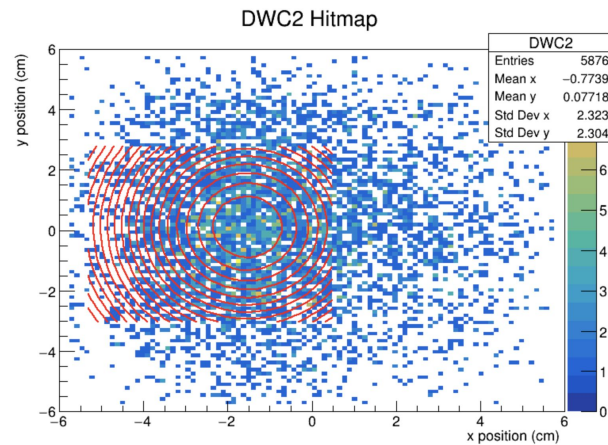

± 1.5 GeV DWC Hitmaps with Adjustable Mangle Array ($r_{\text{mag}} = 1.5$ cm)

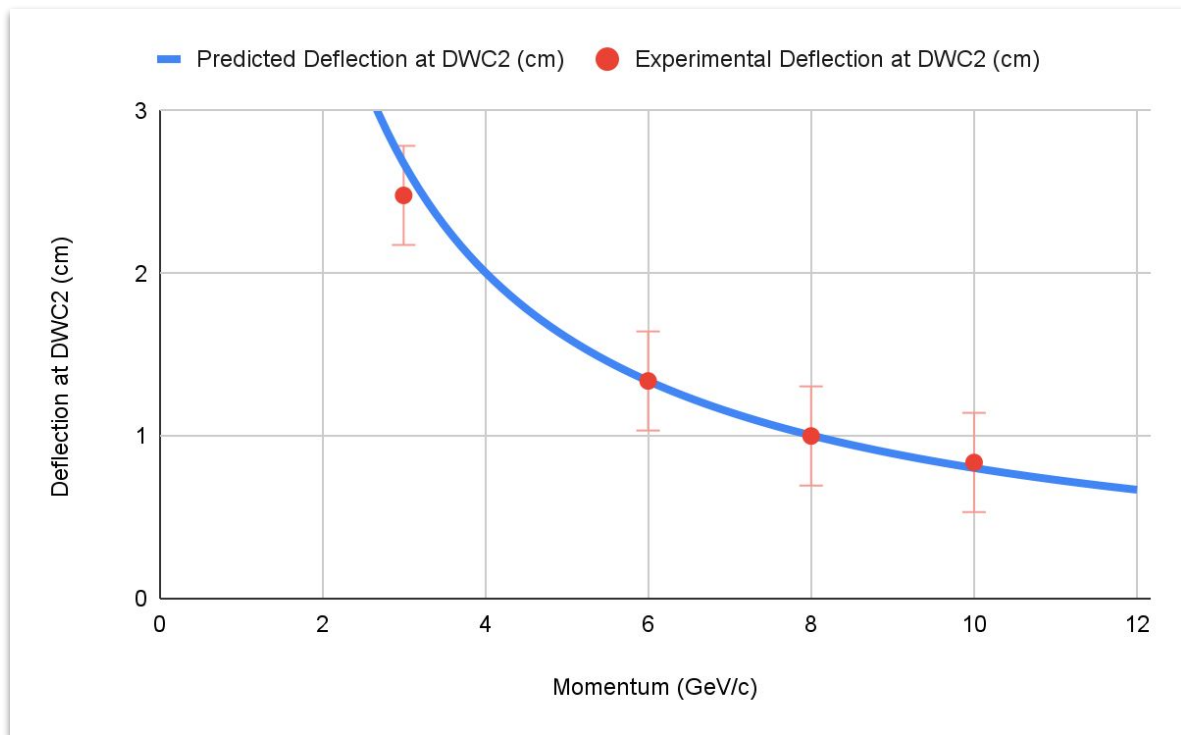

No magnet

Magnet

Experimental vs. Predicted X Deflection ($r_{\text{mag}} = 2.5 \text{ cm}$)

Experimental Error:

Inherent DWC precision	+/- 0.3 mm
Distance from magnet to DWC2	+/- 0.5 mm
2D Gaussian fit	+/- 3 mm

Predicted Error:

Measurement position	+/- 1 mm
Teslameter precision	+/- 1 mT
Linear Interpolation	+/- ~ 5mT

Experimental vs. Predicted X Deflection ($r_{\text{mag}} = 3.5 \text{ cm}$)

Experimental Error:

Inherent DWC precision	+/- 0.3 mm
Distance from magnet to DWC2	+/- 0.5 mm
2D Gaussian fit	+/- 3 mm

Predicted Error:

Measurement position	+/- 1 mm
Teslameter precision	+/- 1 mT
Linear Interpolation	+/- ~ 5mT

Magnet design: introduction (cont'd)

Magnet design: defining the corresponding ideal field

For each set of cross-sectional magnetic field with a given N , we define the corresponding ideal fields (centered at the origin) to be

$$\vec{B}_{dip}(x, y) = [0, B]$$

In the dipole case and

$$\vec{B}_{quad}(x, y) = g[-x, y]$$

In the quadrupole case.

The magnitude of the ideal dipole's flux density, B , is obtained from the flux density at the array center. The ideal quadrupole's magnetic flux gradient, g , is obtained through a linear regression.

Preliminary simulations - Geant4

(a) No magnetic mangle present in beam-line

(b) Dipole configuration with radial arrangement of $d = 6.0$ cm ($B = 0.29$ T)

(c) Quadrupole configuration with radial arrangement of $d = 7.0$ cm ($g = 6.1$ T/m)

Preliminary simulations - Geant4 (cont'd)

Figure 10: GEANT4 simulation: Normalized deflection angle distributions at 1.0 GeV and 2.0 GeV passing through the mangle dipole configuration.
